C. When I tested TCP and UDP connections they had different delay values, UDP was generally faster than TCP. This is due to UDP not requiring a connection establishment while TCP does, which takes time.

D. The delays aren't the same, the two directions can have different delays due to routing difference, packet queuing, or network congestion

E. I observed that the delay can change depending on the location or time of day that the servers are running. When they are working on the same machine the RTT is very small as they don't have to travel through any real network. However, when they are on different machines the RTT is a lot bigger. This is due to congestion as packets have to spend more time in queues as the network usage grows. The number of hops and routing paths can also cause longer delays between client and server.
